

LUMINARY MEMO #339

To: Distribution
From: D. Eyles
Date: 14 April 1972
Subject: Latest EMP 103B

Here is the latest word on EMPs for a failed CDUX. The previous version (Luminary Memo 235, rev. 1), you'll remember, discouraged DAP activity in yaw by enlarging the deadband. This version does it by changing the phase-plane parameters for the p-axis to vastly enlarge the coast region. For good measure CDUX, CDUXD, DELCDUX, OMEGAPD, and DELPEROR are zeroed.

The result is a DAP which is totally quiet in the yaw axis. It does not react to ACA yaw deflections. Control in this axis can be exercised in "direct" without interference from the DAP. Control in the other axes is normal, in auto or attitude-hold, as long as real vehicle yaw is kept close to zero.

The disadvantage of this version, with respect to the old one, is that no acceleration command capability in yaw is available from the autopilot. The advantages are that control in other axes is not prejudiced by enlarging the deadband, and that jet firings are prevented even in such odd runaway cases as that simulated at Grumman. There remains a one-in-five (or less) chance of a jet firing every 2 seconds, if the DAP gets in before the downrpt following the phase-plane set-up in 1/ACCS, but this has had no noticeable effect on control in simulations at Grumman and MIT.

In the now familiar way, the EMP is loaded into vac area 5 and enabled with V 31 E after noun 26 has been appropriately loaded. The EMP, in two forms, follows:

EMP FOR A FAILED CDUX

The EMP quiets PGNCS autopilot activity in the p-axis (yaw) in the event of a frozen or runaway CDUX. The DAP will not respond to stick deflections. Control in yaw can be exercised in the direct mode. Control is normal in other axes as long as real vehicle yaw is kept near zero.
